**Abstract** We determined the acidity constants of tebuconazole and penconazole, two fungicides from the group of 1,2,4-triazoles. Potentiometric titrations were performed in a 20% (v/v) acetonitrile/water mixture at 25 °C and at a fixed ionic strength ( $\text{KNO}_3$ ,  $0.1 \text{ mol} \cdot \text{dm}^{-3}$ ). The  $\text{p}K_{\text{a}}$  values (representing thermodynamic constants) were determined to be  $5.0 \pm 0.1$  and  $5.2 \pm 0.1$  for tebuconazole and penconazole, respectively. These values could be used in pure water solutions to consider the protonated or deprotonated forms when studying the field behavior of these fungicides. Molecular modeling calculations allowed identifying the N4 atom as the protonation site.

**Keywords** Triazole pesticides • Potentiometric titrations • Protonation constant • Protonation site • Molecular modeling

## 1 Introduction

Agrochemicals include organic molecules, with various building blocks and functional groups. When they are dispersed in the field, their physical, chemical and ecotoxicological properties, mostly related to their structure, are of major importance for their environmental behavior. Among those, the acid/base properties are of special interest, because they determine the present chemical form: a neutral molecule or a charged ion (either a cation and/or an anion, depending on the molecular structure). Because the soil and its main components (clays, Fe- and Mn-oxyhydroxides, humic substances, etc.) exhibit different surface charges according to the environmental pH [1], the acidity constant  $K_a$  (or the  $pK_a$ ) of the pesticides are crucial for determining their behavior in the soil environment.

Here we focused on two pesticides of the (benzo)triazole family for which some quantitative structure-properties relationships are already available [2]: tebuconazole and penconazole (Table 1, Fig. 1). They are known to behave as systemic fungicides, with both curative and protective actions, mainly applied to orchards and vineyards [3] where the soil pH is commonly within the range from 4 to 8. According to their structure (Fig. 1), both tebuconazole and penconazole can be expected to behave as weak bases, the N4 nitrogen atom in the 1, 2, 4-triazole ring being the most probable target for protonation (see section 3.1 below); unfortunately, their  $pK_a$  values are unknown (tebuconazole) or of dubious value (penconazole) [4]. The knowledge of their correct values is essential, in order to predict the nature of the species (neutral molecule or protonated one) present in the environment.

These triazole molecules are poorly water-soluble, and require water-miscible co-solvents in order to be solubilized. Acetonitrile is a very adequate cosolvent for use in RP-HPLC analysis of this class of compounds [5, 6] due to its aprotic and polar nature and because it is fully miscible with water. Therefore, a mixture of acetonitrile and water was chosen here for the potentiometric determination of the  $pK_a$  of the two fungicides.

## 2 Experimental

### 2.1 Reagents

Analytical-grade tebuconazole was supplied by the Institute of Industrial Organic Chemistry (Warsaw, Poland) with a purity of  $99.9 \pm 0.1$  %; analytical standard penconazole was purchased from Fluka (Pestanal, 99.1 %). All reagents and acetonitrile (AN) were of analytical grade (Fluka), and dissolved in high purity de-ionized carbonate-free water (Milli-Q system: resistivity  $18.2 \text{ M}\Omega \cdot \text{cm}$ ,  $\text{TOC} < 10 \mu\text{g} \cdot \text{dm}^{-3}$ ).

## 2.2 Potentiometric Measurements

The  $\text{p}K_{\text{a}}$  values of tebuconazole and penconazole were determined by potentiometric titration in a 20% (v/v) acetonitrile/water solvent mixture, according to a slight modification of the method described by Fikri et al. [7]. Each triazole compound (0.01 g) was dissolved in 20% AN ( $100 \text{ cm}^3$ ; at a fixed  $0.1 \text{ mol} \cdot \text{dm}^{-3}$  ionic strength using  $\text{KNO}_3$ ), then sonicated (Bransonic model 200, power = 19 W, frequency = 40 Hz) during 20 min. Nitric acid ( $0.1 \text{ mol} \cdot \text{dm}^{-3}$ ) was added in equivalent amount to  $20 \text{ cm}^3$  of the triazole solution and this mixture of strong acid and protonated weak base was subsequently titrated by  $0.01 \text{ mol} \cdot \text{dm}^{-3}$  KOH (in the 20% AN solvent) in a thermostatted cell ( $25^\circ\text{C}$ ) under nitrogen atmosphere (Linde, 5.0). The exact concentration of the KOH solution was determined by titration with  $\text{HNO}_3$  ( $0.1 \text{ mol} \cdot \text{dm}^{-3}$ ; Normadose Prolabo). The titration was performed (Fig. 2) using the automatic titrator Metrohm 716 DMS Titrino coupled to a Metrohm 727 Ti Stand, a Metrohm 722 stirrer and equipped with a glass/calomel pH electrode (Metrohm, pH 0–14/0–80  $^\circ\text{C}$ ; KCl  $3 \text{ mol} \cdot \text{dm}^{-3}$ ). The set parameters are the dynamic mode, a  $1 \text{ mV} \cdot \text{min}^{-1}$  signal drift and a  $5 \text{ cm}^3 \cdot \text{min}^{-1}$  maximal flow-rate. The titration started after pH equilibrium was reached in the cell. The combined glass electrode was calibrated with pH 7.00 and 4.00 aqueous buffers and then with a  $0.05 \text{ mol} \cdot \text{kg}^{-1}$  potassium hydrogenophthalate solution in the 20% AN solvent ( $\text{pH}_{\text{S}} = 4.58$  [8, 9]). All procedures were performed in triplicates. The titration curves were fitted using the ProtoFit (version 2.1) software [10] to calculate the  $\text{p}K_{\text{a}}$  values and using the Davies activity coefficient corrections calculated from the data in the mixed solvent system [11]. According to Fikri et al. [7], such a calculated value can be considered as numerically equal to the value in pure water, within the experimental uncertainties ( $\pm 0.05$ ).

## 2.3 Molecular Modeling

For each compound, the geometries of the two enantiomers were optimized by molecular mechanics (MM2 force field) with HyperChem [12] and further refined by the PM6 semi-empirical molecular orbital method with MOPAC [13, 14]. The gas phase formation enthalpies at 298 K were also computed from MOPAC.

### 3 Results and Discussion

#### 3.1 Protonation Site

Due to the presence of a single chiral center (asymmetric carbon atom) in both molecular structures, each consists of two (*R* or *S*) enantiomers (Fig. 1), whose properties can be somewhat different; the studied samples were racemic mixtures, however.

According to our molecular theoretical quantum calculations of gas phase formation enthalpies (Table 3), the N4 protonation is favored by *ca.* 50–65 kJ·mol<sup>-1</sup>, compared to N2 protonation, whatever the studied fungicide and its enantiomer form.<sup>1</sup>

Any further protonation on the N2 atom of the triazole ring will be hindered, due to both steric hindrance and electrostatic repulsion. Moreover, there are no other protonable or deprotonable site on neither of these two molecules.

#### 3.2 Protonation Constants

The acidity constants,  $pK_a$ , of the two triazole compounds were determined from potentiometric titrations in a 20% (v/v) AN solvent mixture at 25 °C (Fig. 2). Due to the introduction of activity coefficient corrections during data treatment, our calculated  $pK_a$  values can be considered as the thermodynamic ones.

However it would be more useful to have information about the  $pK_a$  value in pure water. In order to estimate the effect of the 20% AN solvent mixture, we refer to our previous study on amino-2

---

<sup>1</sup> We have also tested the new PM7 method in MOPAC 2012. This method, which is still under development, gave enthalpy values within 5.3% of the PM6 values. The relative stabilities of the protonated forms were unchanged.

pyridine derivatives [7]: it appeared that the values of aqueous  $pK_a$  would be *ca.* 0.02 unit higher than those determined in the 20% AN solvent, what is within the experimental uncertainties ( $\pm 0.05$ ).

This is why we consider that our values are a good estimate (better than  $\pm 0.1$  unit) of the aqueous  $pK_a$  of these two fungicides, *i.e.* for the equilibrium between the protonated and the free molecular triazole ( $\pm 0.1$ ; at 25 °C):

Until now, there has been limited information about the dissociation constant of tebuconazole and penconazole (Tables 1 and 2). According to the IUPAC Pesticides Properties Database [4], tebuconazole is considered as a very weak base, without any numerical value; for penconazole, the low value given (1.51, see Table 1) is not in accordance with the structure of the compound, while it would correspond to a medium-strength acid. Few other data are cited in the literature (see Table 2); in all cases, they are lower than our experimental values, indicating a somewhat weaker basic behavior for the corresponding molecule, what is once more not coherent with its structure. Furthermore, the SPARC-calculated values [15] are too low to be realistic, and should be ignored.

## 4 Conclusion

The aqueous  $pK_a$  values, determined for the first time in this study, allow predicting the environmental behavior of either tebuconazole or penconazole according to the acid/base properties of the soil solution and of the soil sorption complex. If stability constants data become available, their possible complexation with metal cations present in the soil solution or added as pesticides (*e.g.*, Cu [17, 18]) can now be estimated, for a better knowledge of the speciation of these triazole fungicides.
